

Data Science Technical Test

You have been provided with two CSV files:

- A training set "training_set.csv" containing the columns `productId`, `productName`, `longDescription`, `nature_code` and `target_code`.
- A test set "testing_set.csv" containing only the columns `productId`, `productName`, and `longDescription`.

Data Description :

- `productId`: product ID
- `productName`: product title
- `longDescription`: product description
- `nature_code`: internal categorization code for our products
- `target_code`: internal categorization code for the target audience of our products

Instructions:

You are required to build two predictors using the training data. The first predictor should predict the nature of the products, and the second one should predict the target audience of these products.

We expect you to submit a file in '.py' (Python) or '.ipynb' (notebook) format where you detail your code, your thought process for solving this problem and the performance of your models.

Please comment on your code to make it easier to understand.

Apply your predictors to the test data and provide us with a '.csv' file named "FIRSTNAME_LASTNAME_prediction.csv" with the columns `productId`, `nature_predict`, and `target_predict`.

In addition to model performance, we will pay particular attention to **your reasoning and the quality of the code** you provide.
